The schematic diagram illustrates the receiver section of the ICOM IC-7000. It begins with an input filter (BL700) connected to the antenna. The signal then passes through a variable capacitor (C705) and a matching network consisting of a resistor (R722) and a capacitor (C713). The signal is then amplified by a pre-amplifier stage (FL702). The output of the pre-amplifier is connected to a detector and limiter stage (FL702). The signal then passes through a mixer stage (FL702) and a local oscillator (C759, FL702). The output of the mixer is connected to a PLL discriminator (C715, FL702). The PLL discriminator output is connected to a PLL lock detector (C733). The circuit is powered by a 12VDC supply and includes various ground connections and component values.
